Setting up the Text-Only link on your Website

To allow Usablenet Assistive to generate on-the-fly text-only pages you only need to create a new link on your pages and have that link point to the Usablenet Assistive. It will work on static pages, dynamic pages (e.g. asp, jsp), on pages produced by a Content Management System or pages pulled out of a database; on pages with any sort of Web content and even forms.

Visitors to your Website will be able to follow such text-mode links, and then be able to navigate through your Website (within the Web server names limits described in sections How to deploy Usablenet Assistive and Installing the serial number) in text-mode. They will be able at any time to switch back to your real Web pages (i.e. without using Usablenet Assistive at all).

The text-mode link should look like this example:

```html
```

where http://www.mycompany.com/some/page.html is the URL of the page containing the text-mode link (i.e. the one that you are editing) and assistive.usablenet.com is the server name where Usablenet Assistive is running.

If you need to code a text-mode link for a page that should be handed to the browser via an HTTPS connection then you only need to change both occurrences of HTTP with HTTPS, i.e.

```html
<a href="https://assistive.usablenet.com/tt/https://www.mycompany.com/some/page.html" title="text-only page produced automatically by Usablenet Assistive">Text only</a>
```

If you decide to put the "text-mode" link in more than one page, and having to specify each time the actual URL of the page to be transcoded is a hassle (like when you use templates for the page heading that are shared among a large number of pages), then you can adopt the following mechanism.

The "text-mode" link should look like this example:

```html
<a href="http://assistive.usablenet.com/tt/referrer" title="text-only page produced automatically by Usablenet Assistive">Text only</a>
```
